

	There is no particular relationship between the two concepts										
	Best Case, Worst Case and Expected Case actually describe the big O or big Theta time for particular scenarios whereas these asymptotic notations describe the upper, lower and tight bounds for the runtime										
	<b>Space complexity</b>										
	Memory or space required by an algorithm	to create an array - if it is unidimensional, $O(N)$ space complexity; for a 2-D array, $O(N^2)$									
	Stack space in recursive calls counts too. Each call adds a level to the stack and takes up actual memory.	However, just because you have $N$ calls does not mean it will take $O(N)$ time: check the example on Page 41 for more details									
	<b>Drop the constants</b>										
	$O(2N)$ is actually $O(N)$										
	<b>Drop the non-dominant terms</b>										
	$O(N^2 + N)$ becomes $O(N^2)$										
	$O(N + \log N)$ becomes $O(N)$										
	$O(5 \cdot 2^N + 1000N^{100})$ becomes $O(2^N)$										
	$O(x!) > O(2^x) > O(x^2) > O(x \log x) \dots > O(x)$										
	<b>Multi-Parts algorithms: add versus multiply</b>										
	Add:	Non-nested chunk of work A and B	$O(A + B)$	"DO THIS THEN WHEN YOU ARE ALL DONE, DO THAT"							

	Example 10	O( $\sqrt{n}$ ) as the for loop does constant time and runs in O( $\sqrt{n}$ ) time								
	Example 11	O(N) as the recursive process calls from N to N-1 to N-2 and so on until 1								
	Example 12	<b>Approach 1:</b> We make a tree for an example string say 'abcd' and we see that we branch 4 times at the root , then 3 times, then 2 times, and then 1 time. this gives us $4 \times 3 \times 2 \times 1$ leaf nodes. We could say n! leaf nodes for n length string. So, total nodes would be $n \times n!$ as each leaf node is attached to a path with n nodes. Also, string concatenation will also take O(n) time. Thus, the final time complexity in worst case would be O( $n \times n \times n!$ ) = O(( $n + 2$ )!).								
		<b>Approach 2:</b> At level 6, we have $6! / 0!$ nodes; at level 5 we have $6! / 1!$ nodes; at level 4 we have $6! / 2!$ nodes...at level 0, we have $6! / 6!$ nodes. so, the total nodes in the tree in terms of n can be : $n!(\frac{1}{0!} + \frac{1}{1!} + \frac{1}{2!} + \frac{1}{3!} + \dots + \frac{1}{n!})$ . Now, the term in the bracket can be defined in terms of Euler's number: $e$ whose value is around 2.718. The constant e can be dropped further. Thus, the time complexity would be O( $n! \times n$ ) where n is due to permutation; thus, time complexity: O(( $n+1$ )!).								
	Example 13	We have to use the earlier pattern for recursive calls: O(branches^depth) = O( $2^n$ ).  We can also get tighter runtime as O( $1.6^n$ ) if we consider that there might be just one call instead of 2 at the bottom of call stack sometimes.								
	Example 14	From previous example, we deduce that fib(n) takes $2^n$ time. And, we have fib(1) + fib(2) + fib(3) + ...fib(n) = $2^{n+1} - 2$ , thus we can say that the run time is approx. $2^n$ .								
	Example 15	Now, here in this program we are doing memoization due to which the amount of work reduces to looking up fib(i - 1) and fib(i - 2) values in memo array at each call fib(i). Thus, we are doing a constant amount of work n times in n calls, hence time complexity: O(n)								
	Example 16	The runtime is the number of times we can divide n by 2 until we get down to the base case 1. As, we know the number of times we can halve n until we get 1 is O(logN)								
<b>Additional Problems</b>										
	1	The for loop iterates through b, thus time complexity is O(b)								
	2	The recursive call iterates through b calls as it subtracts 1 in each iteration, thus time complexity is O(b)
