	Analyze an algorithm	Testing of programs						
2	**Priori Analysis**	**Posterior Testing**						
	Algorithm	Program						
	Independent of language	Language dependent						
	Hardware independent	Hardware dependent						
	Time and space function	watch time and bytes						
3	**Characteristics of algorithm**							
	Zero or more inputs							
	Must generate atleast one output							
	Definiteness							
	Finiteness							
	Effectiveness							
4	**How to analyze an algorithm**							
	Time							
	Space							
	Network consumtion : Data transfer amount							
	Power consumption							
	CPU registers							
5	**Frequency Count Method**	Used for time snalysis of an algorithm						
	Assign 1 unit of time for each statement							
	For any repitition, calculate the frequency of repetition							
	for(i = 0; i < n; i++) --> condition is checked for n+1 times	2n + 2 units of time ~ n+1 as we see condition i < n only for now						
	any statement within the loop will execute for n times							

	Space complexity depends upon number and kind of variables used							
6	**Algorithm : sum(A, n)**							
	Single for loop -							
	Time complexity: O(N)							
	Space complexity: O(N)							
7	**Algorithm : Add(A, B, n)**	Sum of two square matrices of dimesions nXn						
	Two nested for loops -							
	Time complexity: O(N^2)							
	Outer for loop executes for N+1 times							
	Inner for loop xecutes for N *(N+1) times							
	Any statement within inner for loop executes for (N + 1) * (N + 1) times							
	Space complexity: O(N^2)							
8	**Algorithm : Multiply(A, B, n)**							
	Three nested for loops -							
	Time complexity: O(N^3)							
	Space complexity: O(N^2)							
9	**Different algorithm conditions**							
	For loops							
	for(i = n; i > 0; i--)	n+1 times						
	for(i = 0; i < n; i = i + 2)	n/2 times						
	2 nested for loops where both i and j range from 0 to n	n^2 times						
	2 nested for loops where j ranges from 0 to i	when i = 0; j loop repeats 0 times; when i = 1; j loop repeates 1 times; and so on...total number of repetitions: 0 + 1+ 2+3+4....+n = O(n^2)						
	p = 0; for(i = 1; p<= n; i++){ p = p + i; }	p = k(k+1)/2 --> assuming that the loop exits when p is greater than n --> k(k+1) / 2 > n	~ k^2 > n --> O(root(n))					
	for(i = 1; i < n; i = i *2)	will execute for 2^k times	O(logn)					
		Assume i >= n ; i = 2^k >= n						
		k = logn with base 2						

	for(i = n; i >= 1; i = i/2)	i						
		n						
		n/2						
		n/2^2						
		n/2^3						
		.....						
		n/2^k						
		Assume i < 1 => n / 2^k < 1	~ O(logn) with base 2					
	for(i = 0; i * i < n; i++)	i*i < n						
		i*i > -n						
		i^2 = n --> i = root(n)	~O(root(n))					
	for(i = 0; i < n; i++) {.....}for(j = 0; j < n ; j++){....}	O(n)						
	p = 0; for(i = 1; i < n; i*2){.....} for(j = 1; j < p; j*2){.....}	log n times for upper loop; lop p times for lower loop	~ O(log (logn))					
	for(i = 0; i < n; i++) {.....for(j = 0; j < n ; j*2){....}}	Outer loop repeats n times; inner loop repeats logn times	~O(nlogn)					
	for(i = 1; i < n; i = i*3)		~O(logn) with base 3					
	While loops							
	while vs. do while	do while will execute for minimum one time						
	for and while are almost similar	do while will execute as long as the condition is true; for loop will execute until the condition is false						
	a = 1;							
	while(a < b){ ..... a = a *2;}	1, 2, 2^2, 2^3......2^k repetitions	~O(logb) with base 2					
		assume a > b; 2^k > b ==> k = logb with base 2						
	i = n; while(i > 1) {....i = i/2;}		~O(logn) with base 2					
	i = 1; k = 1; while(k <n){....k = k + i; i++;}							
		i	k					
		1		1				
		2	1 + 1					
		3	2 + 2					
		4	2 + 2 + 3					

		5	2 + 2 + 3 + 4					
	.....							
	m		m(m + 1) /2					
	Assume, k >= n		m(m + 1)/ 2 >= n	~O(root(n))				
	while(m != n) { if(m > n) m = m - n; else n = n - m;}			~O(n)				
10	**Types of time functions**							
	O(1) --- constant							
	O(logn) --- logarithmic							
	O(n) --- linear							
	O(n^2) --- quadratic							
	O(n^3) --- cubic							
	O(2^n) --- exponential							
11	**Order of complexity**							
	1 < logn < root(n) < n < nlogn < n^2 < n^3 <.....< 2^n < 3^n .....< n^n							
12	**Asymptotic Notations**							
	Representation of time omplexity in simple form which is understandable							
	Big O Notation - works as an upper bound		The function f(n) = O(g(n)) iff for all positive constants c and n_0, such that f(n) <= c * g (n) for all n >= n_0; here, f(n) = O(n)	e.g. 2n + 3 <= 10n; All those functions in time order complexity above n become upper bound; below n become lower bound and n is the average bound				

	Big Omega Notation - works as a lower bound	The function f(n) = Omega(g(n)) iff for all positive constants c and n_0, such that f(n) >= c * g(n) for all n >= n_0; here, f(n) = Omega(n)	e.g. 2n + 3 >= 1n		
	Theta Notation - works as an average bound	The function f(n) = theta(g(n)) iff for all positive constants c1, c2 and n0 such that c1 * g(n) <= f(n) <= c2 * g(n)	e.g. f(n) 2n + 3; 1n <= 2n + 3 <= 5n		
	Most useful is theta notation, then why do we need the other two?	In case we are not able to get the average bound, then we point to its upper or lower bound			
13	**Examples for asymptotic notations**				
a	**f(n) = 2n^2 + 3n + 4**				
	2n^2 + 3n + 4 <= 2n^2 + 3n^2 + 4n^2 i.e. 9n^2	O(n^2)			
	2n^2 + 3n + 4 >= 1n^2	Omega(n^2)			
	1n^2 <= 2n^2 + 3n + 4 <= 9n^2	Theta(n^2)			
b	**f(n) = n^2logn + n**				
	n^2logn <= n^2logn + n <= 10n^2logn	O(n^2logn)			
		Omega(n^2logn)			
		Theta(n^2logn)			
c	**f(n) = n!**				
	1 <= 1*2*3*4....*n-1*n <= n*n*n*n*......*n	O(n^n)			
		Omega(1)			
		Cannot find theta for n!			
d	**f(n) = logn!**				
	1 <= log(1*2*3.....*n) <= log(n*n*n*n....*n)	O(logn^n)			
		Omega(1)			
		Cannot find theta for logn!			
14	**Properties of Asymptotic notations**				
	General properties -				
	if f(n) is O(g(n)) then a*f(n) is O(g(n))				
	e.g. f(n) = 2n^2 + 5 is O(n^2), then 7f(n) i.e. 14n^2 + 35 is also O(n^2)	This would be true for both Omega and theta n as well			

	Reflexive property -		
	If f(n) is given then f(n) is O(f(n))		
	e.g. f(n) = n^2 then O(n^2)	A function is an upper bound of itself	
		Similarly, a function is a lower bound of itself	
	Transitive property -		
	If f(n) isO(g(n)) and g(n) is O(h(n)) then f(n) is O(h(n))		
	e.g. f(n) = n; g(n) = n^2 and h(n) = n^3	True for all notations	
	n is O(n^2) and n^2 is O(n^3) then n is O(n^3)		
	Symmetric property -		
	If f(n) is theta(g(n)) then g(n) is theta(f(n))	True for only theta(n)	
	e.g. f(n) = n^2 g(n) = n^2 ; f(n) = theta(n^2) and g(n) = theta (n^2)		
	Transpose symmetric -	True for BigO and Omega notations	
	if f(n) = O(g(n)) then g(n) is Omega(f(n))		
	e.g. f(n) = n and g(n) is n^2 then n is O(n^2) and n^2 is Omega(n)		
	If f(n) = O(g(n)) and f(n) = Omega(g(n)) then g(n) <= f(n) <= g (n) therefore f(n) = theta(g(n))		
	If f(n) = O(g(n)) and d(n) = O(e(n)) then f(n) + d(n) = O(max(g (n), e(n))		
	e.g. f(n) = n = O(n) , d(n) = n^2 = O(n^2) then f(n) + d(n) = n + n^2 = O(n^2)		
	If f(n) = O(g(n)) and d(n) = O(e(n)) then f(n) * d(n) = O(g(n) * e (n))		
15	**Comparison of functions**		
	First method is substituting values for n and comparing		
	Second method is applying log on both sides		
		Properties of log -	
	Example -	logab = loga + logb	
	f(n) n^2logn; g(n) = n(logn)^10	loga/b = loga - logb	
	Apply log	loga^b = bloga	

log(n^2log(n)); log(n(logn)^10)	a^(log_cb) = b^(log_ca)					
log(n^2) + loglogn; logn + loglog^10	a^b = n then b = log_an					
2logn + loglogn ; logn + 10loglogn						
here; 2logn is greater than logn and logn is a bigger term than loglogn						
so, first term is greater than the second one						
f(n) = 3n^(rootn) ; g(n) = 2^(rootn log_2(n))						
Applying log						
3n(rootn) ; (n^rootn)log_2(2)						
3n(rootn) ; nrootn						
first term is greater than the second one value wise but asymptatically they are equal						
f(n) = n^(logn); g(n) = 2^(rootn)						
apply log,						
log(n^logn); log(2^rootn)						
logn*logn ; rootn (log_2(2))						
log^2n ; rootn						
canot judge, so apply log again						
2loglogn; 1/2logn						
loglogn is smaller than logn						
thus, second term is greater						
f(n) = 2^(logn); g(n) = n^(rootn)						
logn*log_2(2) ; rootn*logn						
logn ; rootn*logn						
second term is greater						
f(n) = 2n; g(n) is 3n						
both are equal asymptotically						
f(n) = 2^n; g(n) = 2^(2n)						
applying log						
log(2^n); log(2^2n)						
n; 2n	after applying log, do not cut coefficients					

		second function is greater							
	16	**Best, worst and average case analysis**							
		Example -							
a		**Linear search**							
		A = {8, 6, 12, 5, 9, 7, 4, 3, 16, 18} key = 7							
		In linear search, it will start checking for the given key from left hand side							
		total in 6 comparisons, we would get our key							
		Best case - key element is present at first index							
		Best case time - 1 i.e. B(n) = O(1); Omega(1); Theta(1)							
		Worst case - key element is present at the last index							
		Worst case time - n i.e. W(n) = O(n); Omega(n); Theta(n)							
		Average case = all possible case time / no. of cases							
		average case analysis is very difficult for most of the cases							
		Here, average case time = 1 +2 + 3.... + n/2 = n(n+1)/2n = n+1/2							
		A(n) = n+1/2							
b		**Binary search tree**							
		height = logn							
		time taken for a particular key is logn							
		Best case - element present in the root							
		Best case time - k i.e. B(n) = O(1); Omega(!); Theta(1)							
		Worst case - searching for a leaf element - depends upon the height of the tree							
		Worst case time - logn i.e. O(logn)							
		min w(n) = logn; max w(n) = n							
	17	**Disjoint sets**							
		No common numbers between two sets - intersection is zero							
		Operations - find, union							
		Find - search or check membership							
		Union - Add an edge							
		Krisgal algorithm: If you take an edge and both the vertices belong to the same set, then there is a cycle in the graph							

	Weighted union is used while adding edges and detectig cycle						
	Collapsing find - process of directly linking node to a direct parent of a set is called collapsing find - reduces the time to find						
18	**Divide and conquer - Strategy 1**						
	Strategy - an apprach for solving a problem						
	If a problem cannot be solved, divide it into sub-problems and find a solution for each sub problem, combine the solutions. *One point to note is that each sub problem should be similar to the original problem only.*						
	Recursive in nature						
	Should have one method to combine the solutions of each sub problem						
19	**Problems under Divide and Conquer**						
	Binary search						
	Finding maximum and minimum						
	MergeSort						
	QuickSort						
	Strassen's matrix multiplication						
20	**Recurrence relation 1: T(n) = T(n-1) + 1**						
	void test(int n)						
	{						
	if(n > 0){						
	printf("%d",n);						
	test(n-1)						
	}						
	}						
	test(3)						
	3. test(2)						
	2. test(1)						
	1 test(0)						

	each print statement takes constant time 1 and there are n+ 1 calls made to the function. we can ignore the last call when it is not printing						
	f(n) = n + 1 calls ; O(n)						
	T(n) = T(n-1) + 1; if we ignore if condition						
	Let us solve this relation;						
	if we know T(n-1) , we can get T(n)						
	T(n-1) = T(n-2) + 1						
	T(n) = [T(n-2) + 1] + 1						
	T(n) = T(n-3) + 3						
	....continue for k times						
	T(n) = T(n-k) + k						
	We would stop after k substitutions; now we need to find k						
	Assume n - k = 0; therefore n = k						
	T(n) = T(n-n) + n						
	T(n) = T(0) + n						
	T(n) = n + 1 i.e. theta(n)						
21	**Recurrence relation 2: T(n) = T(n-1) + n (decreasing function)**						
	void test(int n)	T(n)					
	{						
	if(n > 0)		1				
	{						
	for(i = 0; i <n; i++)	n+1					
	{						
	printf("%d", n);	n					
	}						
	test(n-1);	T(n-1)					
	}						
	}						
		T(n) = T(n-1) + 2n + 2 i.e. theta(n)						
	we can also write T(n) = T(n-1) + n for n > 0						
	T(n) = 1 for n = 0						
	T(n)	n time					
	n T(n-1)	n-1 time					
	n-1. T(n-2)	n - 2 time					

	n-2 T(n-3)	n - 3 time					
	....						
	T(2)						
	2 T(1)	2 units of ti me					
	1 T(0)	1 unit of time					
	for T(0) it does nothing	0 unit of time					
	time taken -						
		0 + 1 + 2 +.....+ n-1 + n					
	theta(n^2)	*T(n) = n(n + 1)/2*					
	T(n) = T(n-1) + n						
	T(n-1) = T(n-2) + n-1						
	thus, T(n) = T(n-2) + (n-1) + n	**remember, don't add the terms					
	T(n) = T(n-3) +(n-2) + (n-1) + n						
	T(n) = T(n-k) + (n-(k-1)) + (n-(k-2))....+(n-1) + n	if we continue for k times					
	assume n - k = 0; n = k						
	Thus, T(n) = T(n-n) + (n - n + 1) + (n - n + 2)..... +(n-1) + n						
	T(n) = T(0) + n(n+1)/2						
	T(n) = 1 + n(n+1)/2	*theta(n^2)* ; this extra 1 is owing to the calls					
22	**Recurrence relation 3: T(n) = T(n-1) + logn**						
	void test(int n)	T(n)					
	{						
	if(n>0)						
	{						
	for(i = 1; i <n; i = i*2)						
	{						
	printf("%d", i);	log n times					
	}						
	test(n-1);	T(n-1)					
	}						
	}						
	T(n) = T(n-1) + logn for n > 0						
	T(n) = 1 for n = 0						
	Solve using tree method,						

	T(n)	
	logn T(n-1)	
	log(n-1) T(n-2)	
	log(n-2) T(n-3)	
	......	
	log2 T(!)	
	log 1 T(0)	
	logn + log(n-1) + ...+ log2 + log1	
	log[n(n-1)(n-2)....2.1] = log(n!)	there is no tight bound for this function but there is an upper bound for it
	O(nlogn)	
	Solving using induction method.	
	T(n) = T(n-1) + logn	
	T(n) = T(n-2) + log(n-1) + log(n)	
	T(n) = T(n-3) + log(n-2) + log(n-1) + logn	
	.....	
	T(n) = T(n-k) + logn + log(n-1) +....log1	
	Asume n-k = 0	
	T(n) = T(0) + logn!	
	T(n) = 1 + logn!	
	O(nlogn)	
23	*How to get the direct answer for a recurrence relation?*	
	T(n) = T(n-1) + 1	O(n)
	T(n) = T(n-1) + n	O(n^2)
	T(n) = T(n-1) + logn	O(nlogn)
	T(n) = T(n-1) + n^2	O(n^3)
	T(n) = T(n-2) + 1	O(n/2) ~ O(n)
	T(n) = T(n-100) + n	O(n^2)
	T(n) = 2T(n-1) + 1	???
24	**Recurrence relation 4: T(n) = 2T(n-1) + 1**	
	Test(int n)	T(n)
	{	

if(n > 0)	1

	thus, m/2^k = 1							
	m = 2^k							
	k = log m with base 2							
	substituting value of n							
	m = logn with base 2							
	therefore, k = loglogn with base 2							
	theta(loglogn with base 2)							
32	**Binary Search Iterative Method**							
	To perform binary search, the prerequisite is that the list must be in sorted order	A = {3, 6, 8, 12, 14, 17, 25, 29, 31, 36, 42, 47, 53, 55, 62}						
	we need two index pointers, one is low at the starting point and the other is high at the end point	l = 1, h = 15 (lowest and highest index); mid = 8						
	mid = low + high / 2 and we take the floor value	key value = 42; A[mid] = 29 --> key > A [mid]						
	the key value is on the right hand side as key value is greater than A[mid]							
	we will change low to mid + 1	l = 9, h = 15; mid = 9 + 15 / 2 = 12						
		A[mid] = 47 > key						
	we will change high to mid - 1 as key < A[mid]							
		h = 11, l = 9, mid = 10; A[mid] = 36						
		A[mid] < key						
	we will change low to mid + 1	l = 11; h = 11; mid = 11; A[mid] = 42						
	we can return the index as we have found the key value	A[mid] = key						

	therefore, binary search looks faster than linear search. It just took 4 comparisons							
	int BinSearch(A, n, key)							
	{							
	l = 1, h = n							
	mid = l + h / 2 - take floor value							
	while(l <= h){							
	if(key == A[mid])							
	{ return index i.e.element is found}							
	else if(key < A[mid])							
	{h= mid-1;}							
	else {							
	l = mid + 1;}							
	}							
	return 0;							
	}							
	Time taken for binary search = logn							
	min time: O(1)							
	max time: O(logn)							
	avg time = add time for each element and divide by number of elements							
33	**Binarysearch Recursive method**							
	Alogirthm RBinarySearch(l,h,key)	T(n)						
	{							
	if(l==h)		1					
	{							
	if(A[low]== key)							
	{							
	return l;							
	}							
	else							
	{							
	return 0;							

		}						
		else						
		{						
		mid = l + h / 2 //taking floor value	1					
		if(key == A[mid])	1					
		{return mid;}						
		if(key < A[mid])	1

		}						
		}						
			T(n) = 1; n =1					
			T(n) = T(n/2) + 1 for n > 1					
			theta(logn)					
	34	**Heaps**						
a		**Representation of a binary tree using an array**						
		T {A, B, C, D, E, F, G}						
		if a node is at index i;						
		its left child is at node 2*i						
		its right child is at node 2*i + 1						
		its parent is at node i/2						
		if there are missing nodes, we leave a blank in its place in the array						
b		**Full binary tree**						
		In its hieght, it has maximum number of nodes and if we wish to add a node, height would increase						
		Max no. of nodes = 2^h - 1						
c		**Complete binary tree**						
		there is no missing element from first element to the last element in array representation of the binary tree						

		Every full binary tree is also a complete binary tree						
		A complete binary tree is a full binary tree until height h - 1						
		Height of a complete binary tree would be minimum i.e. logn						
d		**Heap**						
		Heap is a complete binary tree						
		Max Heap: every node has value greater than all its descendants {50, 30, 20, 15, 10, 8, 16}						
		Min Heap: every node has value smaller or equal to than all its descendants {10, 30, 20, 35, 40, 32, 25}						
	35	**Insert operation in a max heap**						
		Insert 60 in the above given max heap						
		this value should be inserted in the last free space in the array						
		i.e. left child of the left most leaf node						
		Then, adjust the elements to make it as a heap						
		So, compare and move 60 up the levels and in the array check at i/2 indices where initially i would be the last empty index where 60 was inserted						
		Time taken would be equal to the number of swaps						
		this depends upon the height of the tree i.e. logn, hence O(logn)						
		minimum time is of no swaps O(1); max would be O(logn)						
	36	**Delete operation in a max heap**						
		From the heap, we need to remove the root / top most element only						
		The last element in the complete binary tree would come in its place						
		Adjust the elements to maintain heap order						
		From the root towards the leaf, adjust						
		Compare the children (2i and 2i +1) and whichever child is greater than compare with the parent						
		Time taken depends upon the height; max could be O(logn)						
		Whenever you delete from max heap, you get the next max element and in case of min heap, it would be the next min element						
	37	**HeapSort**						

	For a given set of numbers, create a heap					
	Delete all the elements from the heap					
	Total N elements we have inserted; each element we assume is moved up to the root; so time taken O(NlogN)					
	Then we delete the elements					
	Store deleted elements in the array in free space in the end					
	Deletion also takes O(NlogN) time					
	Thus, heapsort takes O(NlogN)					
38	**Heapify**					
	The process of creating heap but direction is opposite than creating a heap					
	O(N)					
39	**Priority Queue**					
	elements will have priority and they would be inserted and deleted as per the priority order					
	For min heap, smaller the no. higher the priority					
	For max heap, greater the no. higher the priority					
	O(logN) for insertion and/or deletion					
40	**TwoWay MergeSort - Iterative method**	Algorithm Merge(A, B, m, n)				
	merging two sorted lists to get a sorted result	{i = 1, j = 1, k = 1;				
	A = {2, 8, 15, 18} i	while(i <= m && j<=n){				
	B = { 5, 9, 12, 17} j	if(A[i] < B[j])				
	Compare A(i) with B(j) to get C(k) and move to next location	{				
	m + n elements are obtained , thus theta(m + n)	C[k++] = A[i++];				
		}				
		else {				
		C[k++] = B[j++];				
		}				
		for(; i <=m; i++){				
		C[k++]=A[i];				
		}				
		for(;j<= n;j++){				
		C[k++] = B[j];				
		}				

		}						
41	**Merging more than two lists**							
	M-way merging							
	A = {4, 6, 12}							
	B = {3, 5, 9}							
	C = {8, 10, 16}							
	D = {2, 4, 18}							
	One way is that we merge A and B; C and D and then finally merge the two resulting lists --> so we perform merge three times here							
	Another way is that we first merge A and B; then we merge resulting list with C ; and the resulting list with D							
	Two-way mergesort is an iterative process whereas mergeSort is a recursive process							
	A = {9, 3, 7, 5, 6, 4, 8, 2} - given an array and we have to sort them using 2-way mergesort							
Ist pass	We would consider each element as a sorted list and merge	merged n elements in this pass						
	First select two lists 3 and 9; then merge them - 3, 9							
	Similarly, we select two lists 7 and 5 , merge them - 5 and 7							
	Another lists we get are {4, 6} and {2, 8}							
	Now, we have 4 lists with two elements each							
2nd pass	When we merged we kept the resulting 4 lists in another array B; B = {{3, 9}, {5, 7}, {4, 6}, {2, 8}}	merged n elements in this pass						
	We merge two lists each							
3rd pass	C = {{3, 5, 7, 9}, {2, 4, 6, 8}}	merged n elements in this pass						
	we merge the above two lists to get a single sorted list							
	D = {2, 3, 4, 5, 6, 7, 8, 9}							
	log(no of elements) = no. of passes							
	Time complexity: O(n(logn))							
42	**MergeSort**							
	A = {9, 3, 7, 5, 6, 4, 8, 2}	Algorithm MergeSort(l, h){	T(n)					
	If there is a single element, we can consider it as a base or small problem {Divide and conquer}							
		if(l < h){						

		mid = (l + h) / 2;	1					
		MergeSort(l, mid);	T(n/2)					
		MergeSort(mid + 1, h);	T(n/2)					
		Merge(l, mid, h);	n					
		}	T(n) = 2T (n/2) + n for n > 1					
		}	T(n) = 1 for n = 1					
	time complexity: theta(nlogn)		using master's theorem, a = 2, b = 2, k = 1					
	merging is done in post order traversal		loga with base b = 1 = k					
			thus, it is case 2					
			theta(nlogn)					
43	**Pros of MergeSort**	**Cons of MergeSort**						
	works great for Large size lists	Extra space (not inplace sort)						
	suitable for Linked List	no small problem						
	supports external sorting	recursive and uses a stack (need n + logn space) i.e. space complexity: O(n + logn) where n is the extra space and logn is the stack space						
	stable: the order of duplicates is maintained							
		insertion sort (O(n^2))						
		mergesort O(nlogn)						
		for small problems, n <= 15; insertionsort works better --> use insertion sort						
43	**QuickSort**							
	students arranging themselves in increasing order of heights							
	10 80 90 60 30 20							
	5 6 3 4 2 1 **9**							
	4 6 7 **10** 16 12 13 14							
	A = {10, 16, 8, 12, 15, 6, 3, 9, 5, INFINITY}	partition(l, h){						
	select first element as a pivot	pivot = A[l];						

	pivot = 10	i = l; j = h;
	we need to find the sorted position for 10	while(i<j){do
	i starting form pivot and j starting from infinity	{
	i would check for elements greater than 10; j would heck for elements smaller than pivot	i++;
	we are using the partitioning procedure	} while(A[i]<= pivot);
	increment i until next vlue is greater than 10 and decrement j until next value is smaller than pivot; stop and swap	do
	{10, 5, 8, 9, 3, 6, 15, 12, 16}	{
	send pivot element at j position	j--;
	now, we can sort the two lists around the partitioning position by performing quicksort recursively	}while(A[j] > pivot);
		if(i<j){
	QuickSort(l, h)	swap(A[i], A[j]);
	{	}
	if(l < h)	swap(A[l], A[j]);
	{	return j;
	j = partition(l, h);	}
	QuickSort(l, j);	
	QuickSort(j+ 1, h);	
	}	
	}	
44	**QuickSort Analysis**	
	suppose it is partitioning in the middle of 1 and 15th index	
	then, two partitions: [1, 7] ; [9, 15]	
	further partitions: [1, 3]; [5, 7]; [9, 11]; [13, 15]	
	at each level , n elements are being handled	
	and there are logn levels	
	thus time complexity for best case: O(nlogn)	
	median : middle element of a sorted list	
	best case of quicksort is that the partitioning occurs exactly at the middle	
	worstcase: if we have an already sorted list	
	time complexity for worstcase: O(n^2)	
	to handle this, try taking middle element as a pivot	

	2. select random element as a pivot						
45	**Strassen's matrix multiplication**						
	A = [a11 a12

	Strategies used for solving optimization problems - Greedy Method, Dymanic programming, branch and bound						
46	**Greedy method**						
	Design wich we can adopt to solve similar problems		Greedy method says that each problem should be solved in stages - each stage we give an input, check if the solution is feasible then we pick it up and move to next stage				

	Solving optimization problems		Algorithm Greedy(a, n) a = {a1, a2, a3, a4, a5} ; n = 5
	Optimization problem: Problems which require either minimum or maximum result		{
	Suppose we have a problem P where we need to travel from source A to destination B, we can have several solutions such as walking on foot, travel by an airplane, ride on a bike, travel by a bus, drive on a car, go by a train and so on..... Now, we notice that we also have some constraints. The solutions that satisfy the conditions given in a problem are called **feasible solutions**	Minimum cost journey - "**Minimization problem**"; then feasible solutions giving minimum cost are called **optimal solutions**. **There can be many feasible solutions but only one optimal solution**	for i = 1 to n do {x = select(a):
	Example: selecting a car to purchase	Example: Hire a person for your company	if feasible(x) then
	Method 1: Looking at all the models available in the city	Method 2: Conduct an assessment center to filter people at each stage and get the best person	{
	Method 2: Checking for the features of the cars and filtering and selecting based on your preferences - greedy method	So, the person may not be the best but the approach is greedy here as we are using our criteria and constraints to choose the best person	solution = solution + x;
47	**Knapsack problem**		}
	n = 7; m = 15	Bag capacity is 15 kgs and we have been given 7 objects. we have to fill this bag with these objects. Profit is the gain we get by transferring this object. Problem is a container loading problem. Problem is filling the container with the objects as the capacity of container is limited	}
Objects	{0 1 2 3 4 5 6 7 }	Optimization and maximization problem	}
Profits	{P 10 5. 15 7 6 18 3 }	Constraints : Bag weight limit	
Weights	{W 2 3 5 7 1 4 1 }		
Profit by weight	{P/W 5 1.3 3 1 6 4.5 3}		
0<=x<= 1	Objects are divisible i.e. we can take just half kg of object 1 and may be 2 kgs of object 2 and so on		
x	()		
	x1 x2 x3 x4 x5 x6 x7		
Method 1	Take the thing that have maximum profit		

Method 2	Take things with smaller weight so that you can put in more things							
Method 3	Take things that have highest profit by weight							
	Let's use method 3							
	First, I include object 5 that has maximum profit by weight. Then I check remaining weight I can put in. We can still put in 14 kgs. Then we select all the quantity of object 1. Remaining weight limit 12 kgs. Add all of object 6. Remaining weight limit 8 kgs. Add all of object 3. Remaining weight limit 3 kgs. Add all of object 7. Remaining weight limit is 2 kgs. Add 2/3 of object 2 as we have only 2 kgs limit remaining.							
x	(1 2/3 1 0 1 1 1)							
	Calculate total profit and verify weight							
	Total weight = 1*2 + 2/3*3 + 1*5 + 0*7 + 1*1 + 1*4 + 1*1 = 15	//Multiplying x elements by Weight w for each object						
	Total profits = 1*10 + 2/3*5 +1*15 + 1*6 + 1*18 + 1*3 = 54.6	//Multiplying x elements by Profit P for each object						
48	**0/1 Knapsack problem**							
	Objects are indivisble and fractions are not allowed i.e. either you include the whole thing or you do not include it at all							
49	**Job sequencing with deadlines**	n = 5 (tasks)						
Jobs	J1 J2 J3 J4 J5							
Profits	20 15 10 5 1							
Deadlines	2 2 1 3 3							
	Assume that there is a machine, on which each job has to be processed and each job takes 1 unit of time (hour) for completion							
	Set of the jobs which can be completed within their deadlines such that profit is maximized	Constraints: deadlines must be met						
deadlines	0---------1-----------2-----------3	maximum 3 slots / jobs						
time slots	9am------10am-----11am-----12am							
Jobs chosen	J2 J1 J4							
Profits	15 + 20 + 5 = 40							
Sequence	J1 --> J2 ---> J4 || J2 --> J1 --> J4							

Job consider	Slot assign	Solution	Profit				
J1	[1,2]	J1	20				
J2	[0,1][1,2]	J1J2	20 + 15				
J3	[0,1][1,2]	J1J2	20 + 15				
J4	[0,1][1,2][2,3]	J1J2J4	20 + 15 + 5				
J5	[0,1][1,2][2,3]	J1J2J4	20 + 15 + 5				
50 **Job sequencing with deadlines another example**		n = 7 (jobs)					
Jobs	J1 J2 J3 J4 J5 J6 J7						
Profits	35 30 25 20 15 12 5						
Deadlines	3 4 4 2 3 1 2						
deadlines	0..........1...........2.............3............4	4 SLOTS AVAILABLE					
Jobs chosen	J4 J3 J1 J2						
Profits	20 25 35 30	110					
51 **Optimal Merge Patern**							
	A = {3, 8, 12, 20}						
	B = {5, 9, 11, 16}						
	C = {3, 5, 8, 9, 11, 12, 16 20}	How merging works for two sorted lists ; time = theta(m + n)					
	what happens if we have 4 lists?						
List	A B C D						
Sizes	6 5 2 3						
Choice 1	We can merge at a time two lists - first A and B; the merge it with C and finally with D. total cost= 11 + 13 + 16 = 40						
Choice 2	Merge A anb; C and D that gives cost 11 and 5 respectively. Merge resulting two lists which will cost 16. Total cost would be 11 + 5 + 16 = 32						
Choice 3	Merge Cand D, resulting list is merged with B and then finally with A; total cost = 5 + 10 + 16 = 31						
optimal method	Always merge two small sized lists , then combined time would be reduced						

Example:										
List	x1	x2	x3	x4	x5					
Sizes	20	30	10	5	30					
Increasing order of sizes	5	10	20	30	30					
Lists	x4	x3	x1	x2	x5					
	First x4 and x3 are merged, cost = 15; then result is merged with x1; cost = 35; x2 and x5 are merged with cost = 60; the two resulting lists are merged with cost = 95									
Total cost	15 + 35 + 60 + 95 = 205									
	3*5 + 3*10 + 2*20 + 2*30 + 2*30 = 205				//multiplying distance of each node and size of each node					
52	**Huffman Coding**									
	Compression technique used to reduce the size of data or message									
Message	BCCABBDDAECCBBAEDDCC									
	Length = 20									
	it has to be sent using ASCII codes (8- bit)									
	A 65 01000001				Size = 8*20 = 160 bits					
	B 66 01000010									
	C 67									
	D 68									
	E 69									
	Can we use our own codes instead of ASCII codes?									
	Fixed size method									
Character	A	B	C	D	E					
Count	3	5	6	4	2	Total count = 20				
Code	000	001	010	011	100					
message	BCCABBDDAECCBBAEDDCC									
bit code	001010....				size = 20*3 = 60 bits					
					5*8 = 40 bits for ASCII code translations					
					5*3 = 15 bits --> our assigned codes					

			40 + 15 = 55 bits					
			message: 60 bits					
			chart: 55 bits					
			total message size: 115 bits					
			so, the message size reduced from 160 bits to 115 bits					
			thus, 40% reduction in size with fixed sized code					
	Huffman coding - variable sized code		element that appears more / often should have a smaller sized code					
character	A B C D E							
count	3 5 6 4 2							
code								
	first, arrange the letters with increasing count / frequency							
character	E A D B C							
count	2 3 4 5 6							
code	000 001 01 10 11		Merge two smaller ones, we get 5, then combine with D, we get 9. Combine B and C , we get 11. Finally, combine two resulting lists , we get 20.					
bit count	6 9 8 10 12		On left side paths, mark as 0 and on right side mark as 1					
total bits for message	45 bits		Bit count for message can also be obtained from the tree, by counting number of edges for a letter and multiplying by the number of occurences for that letter in the message i.e. summation of distance and frequency of a letter					
ASCII codes for chart	5*8 = 40 bits							
assigned codes	12 bits							
total bits for tree/table	52 bits							
Size of total msg	52 + 45 = **97 bits**							
Message transferred	0011111011011110010110001111010001010000110		A tree or a table would be needed along with it					
Decoding	BCCD...							

53	**Minimum Cost Spanning Tree**		
	G = (V, E)		
	V = {1, 2, 3, 4, 5, 6}	|V| = n = 6	
	E= {(1,2), (2,3), (3,4), (4,5), (5, 6), (6,1)}	|V| - 1 = 5 edges	
	the tree should not have a cycle		
	S is a subset of G, WHERE IN S = (V', E')	V' = V; |E'| = |V| - 1	
	Number of edges in graph = 6 out of whch I have to select 5 edges for spanning tree - thus i can select in **6C5 ways**	Suppose we have 7 edges, out of which the seventh edge (3,5) divides the graph into two cycles of less tha 6 vertices, then we can select 5 edges for spanning tree in **7C5 - 2 ways**	
General formula	|E|C(|V|-1) - no. of cycles		
	Now, if we have a weighted graph, I wish to know the number of possible spanning tree		
	Vertices = 4		
	Edges = 3		
	cost = 14		
	similarly , depending upon the edges we select, cost may vary each time		
	Can I found the minimum cost spanning tree?		
Method 1	Try all possible spanning trees and get the minimum cost spanning tree		
Method 2	Prim's algorithm (Greedy method)		
Method 3	Kriskal's algorithm (Greedy method)		
Method 2:	**Prim's algorithm**		
	Select the minimum cost edge from the graph first	(6,1) ; w = 10	
	Then, following this select minimum cost edge but make sure it is connected to previously chosen vertices	(5, 6); w = 25	
		(5, 4); w = 22	
		(4, 3); w = 12	
		(3, 2); w = 16	
		(2, 7); w = 14	
	Now, if we add costs of all the chosen edges, total cost = 99		

	For non connected graphs we cannot find the minimum cost spanning tree or spanning tree							
Method 3	**Kruskal's method**							
	Always select smallest cost edge							
	(1,6); w = 10							
	(3, 4); w = 12							
	(2, 7); w = 14							
	(2, 3); w = 16							
	(4, 5); w = 22							
	(5, 6); w = 25							
	total cost = 99							
	vertices count : |V|	To get a minimum cost edge each time, min heap can be used						
	edges count: |V| - 1	theta(nlogn)						
	theta(|V||E|)							
	theta(n.e) = theta(n^2)							
	for non-connected graphs, spanning tree cannot be found							
	Kruskal algo may give spanning tree for those non connected componr=ents but bot for the graph as a whole							
	if in a certain graph, certain edges' weights are missing, then use the given weights of remaining edges to guess the weight							
54	**Dijkstra algorithm**							
	Single source shortest path to all the vertices							
	find the shortest path to a vertex annd update it to other vertices. this updation is called relaxation							
	Relaxation							
	if(d[u] +c(u,v) < d[v]){ d[v] = d[u] + c(u,v)}							
	no of vertices = |V|							
	at most no. of vertices relaxing = |V|							

worst case time of Dijkstra algorithm: theta(n*n)

Example - starting vertex is 1

selected vertex	2	3	4	5	6
4	50	45	**10**	infinity	infinity
5	50	45	**10**	**25**	infinity
2	45	45	**10**	**25**	infinity
3	45	45	**10**	**25**	infinity
6	45	45	**10**	**25**	infinity

Another example - starting vertex is 1

selected vertex	{2,	3,	4}
2	{3,	infinity,	5}
4	{3,	infinity,	5}
3	{3,	7,	5}
	{3,	7,	5}

Another example - starting vertex is 1

selected vertex	{2,	3,	4}
2	{3,	infinity,	5}
4	{3,	infinity,	5}
3	{3,	7,	5}
	{-3,	7,	5}

Dijkstra algorithm might work or might not work in case of en edge having negative weightage

55 **Dynamic programming**

Dynamic programming vs greedy method

	In Greedy method, we try to follow a predefined procedure that gives us the best / optimal result. The procedure is already known for optimization. But, in dynamic programming, we try to get all the solutions and then decide the best solution. Mostly dynamic programming questions are solved using recursive procedures. They follow a prnciple of optimality. In greedy method, decision is taken just once and followed through whereas in dynamic programming, decision is taken at each step						
	Example:						
	Fibonacci series						
	fib(n) = 0 if n = 0	T(n) = 2T(n-1) + 1{Approximating T(n-2) ~ T(n-1) here}					
	fib(n) = 1 if n = 1	Time taken would be O(2^n) by using Master's theorem					
	fib(n) = fib(n-2) + fib(n-1) if n > 1	Why can't we reduce the function calls to reduce the time taken?					
		For this, we would take a global array and initially fill it with -1					
	int fib(n) {	F = {-1,-1,-1,-1,-1}					
	if(n<= 1){	Then, as the function calls f(1), mark it as 1					
	return n;}	Then f(0) is marked as 1					
	return fib(n-2) + fib(n-1);	Then use the stored result to get the rest.					
	}	Finally, F would get updated as we solve: F = {0, 1, 1, 2, 3, 5}					
		Total 6 calls are made then i.e. n+1 calls i.e. O(n)					
		This is called result of memorization					
	From the above example, we can see reduction in number of calls from O(2^n) to O(n) using memorization. It follows top down approach. The same problem can be solved using tabular method (iterative process) as shown below:						
	int fib(int n) {						
	if(n <= 1) {						
	return n;}						
	F[0] = 0; F[1] = 1;						
	for(int i = 2; i <= n; i++){						
	F[i] = F[i-2] + F[i - 1];						
	}						
	return F[n];						
	}						

	F= {0, 1, 1, 2, 3, 5}		
	This is a bottom - up approach i.e. starting from F[0] and moving to F[n]		
56	**Multistage Graph**		
	A multistage graph is a directed weighted graph. The vertices are divided into stages such that the edges are connecting vertices from one stage to next stage only. First stage and last stage will have only one vertex to represent start and end point. This is usually used to represent resource allocation.		
	The objective of the problem is that I have to select a path which gives me minimum cost.	//it is a minimization or optimization problem	
	Dymanic programming works on principle of optimality. Principle of optimality says that a problem can be solved in a squence of decisions.		
	From first stage I have to select one optimal vertex that leads to minimum cost and I have to take this decision at each stage. Thus, I can apply dynamic programming here.		

V	1	2	3	4	5	6	7	8	9	10	11	12	
Cost	16	7	9	18	15	7	5	7	4	2	5	0	cost(5, 12) = 0 ; here 5 is the stage and 12 is the vertex
d		2/3	7	6	8	8	10	10	10	12	12	12	12	cost(4, 9) = 4

		cost(4, 10) = 2
	Formula for multistage graph:	cost(4, 11) = 5
	cost(lth stage, jth vertex no.) = cost(i, j) = min{C(j, l) + cost(i+1, l)}	cost(3, 6) = min{ C(6, 9) + cost(4, 9) , C(6, 10) + cost(4, 10)} = min{6 + 4, 5 + 2} = 7
		Similarly, cost(3, 7) = min{8, 5} = 5
	Now, we will solve it by going in forward direction and taking decisions based on above data;	cost(3, 8) = min{7, 11} = 7
	d(1,1) = 2	Similarly, cost(2, 2) = min{C(2, 6) + cost(3, 6), C(2, 7) + cost(3, 7), C(2, 8) + cost(3, 8)} = min{11, 7, 8} = 7
	d(2,2) = 7	cost(2, 3) = min{9, 12} = 9
	d(3, 7) = 10	cost(2, 4) = min{18} = 18
	d(4, 10) = 12	cost(2, 5) = min{16, 15} = 15
	Path: 2---> 7---> 10----> 12	cost(1,1) = min{16, 16, 21, 17} = 16
	d(1, 1) = 3	
	d(2, 3) = 6	
	d(3, 6) = 10	
	d(4, 10) = 12	
	Path: 3---> 6---> 10----> 12	

	So, we have two paths with same cost.									

57 Multistage Graph (Program)

Cost adjacency Matrix

	0	1	2	3	4	5	6	7	8
0	0	0	0	0	0	0	0	0	0
1	0	0	2	1	3	0	0	0	0
2	0	0	0	0	0	2	3	0	0
3	0	0	0	0	0	6	7	0	0
4	0	0	0	0	0	6	8	9	0
5	0	0	0	0	0	0	0	0	6
6	0	0	0	0	0	0	0	0	4
7	0	0	0	0	0	0	0	0	5
8	0	0	0	0	0	0	0	0	0

	0	1	2	3	4	5	6	7	8
cost	--	9	7	11	12	6	4	5	0
d	--	2	6	6	5	8	8	8	--
path	--	1	2	6	8				

Path is calculated using the following formula: p[i] d[p[i-1]] ; p[2] = d[p[2-1]] = d[1] = 2

time complexity: O(n^2)

```
main(){
int stages = 4, min;
int n = 8;
int cost[9], d[9], path[9];
int c[9][9] = {{0,0,0,0,0,0,0,0,0},
{0,0,2,1,3,0,0,0,0}, {0,0,0,0,0,2,3,0,0}, ......}
cost[n] = 0;
for(int i = n-1; i >=1; i--){
min = 32767;
for(int k = i + 1; k <= n; k++){
if(C[i][k] != 0 && C[i][k] +C[k] < min){
min = C[i][k] +C[k] ;
d[i] = k;
}
}
cost[i] = min;
}
p[1] = 1; p[stages] = n;
for(i = 2; i < stages; i++){
p[i] = p[d[i-1]];
```

58 All Pairs Shortest Path

If I use Dijkstra algorithm on each vertex to find the shortest path of all, the time complexity would be O(n^3).

A0 =

	1	2	3	4
1	0	3	INF	7
2	8	0	2	INF
3	5	INF	0	1
4	2	INF	INF	0

Considering vertex 1 as intermediate vertex   A0[2,3]   A0[2,1] + A0[1,3]

A1 =

	1	2	3	4

2   <   8   +   INF

1	0	3	INF	7							
2	8	0	2	15	A0[2,4]	A0[2,1] + A0[1,4]					
3	5	8	0	1	INF >	8 + 7 = 15					
4	2	8	INF	0							
					A0[3,2]	A0[3,1] + A0[1,2]					
	Considering vertex 2 as intermediate vertex				INF >	5 + 3 = 8					
A2 =	**1**	**2**	**3**	**4**							
1	0	3	5	7	A[1,3]	A[1,2] + A[2,3]					
2	8	0	2	15	INF <	3 + 2 = 5					
3	5	8	0	1							
4	2	5	7	0	for(k = 1; k <= n; k++){						
					for(i = 1; i <= n; i++){						
	Considering vertex 3 as intermediate matrix				for(j= 1; j <= n; j++){						
A3 =	**1**	**2**	**3**	**4**	A[i,j] = min(A[i,j], A[i,k] + A[k,j])						
1	0	3	5	6	}						
2	7	0	2	3	}						
3	5	8	0	1	}						
4	2	5	7	0							
	Considering vertex 4 as intermediate matrix										
A4 =	**1**	**2**	**3**	**4**							
1	0	3	5	6							
2	5	0	2	3							
3	3	6	0	1							
4	2	5	7	0							

Formula used to make the above matrices:

$A[i,j] = min\{A[i,j], A[i,k] + A[k, j]\}$

time complexity = O(n^3)

59 Matrix chain multiplication

A1 . A2 . A3 . A4

(5X4) (4X6) (6X2) (2X7)

For generating a single matrix C after single multiplication of 2 matrices of order (5X4) and (5X3) , we would need to do 60 multiplications

((A1.A2).A3).A4

or (A1.A2).(A3.A4)

or ....there could be several ways

then, how to choose theright way?

T(n) = 2nCn/n+1   trees are possible

thus, with 3 nodes ; T(3) = 5

Using tabular approach (bottom up apprach),

m

	1	2	3	4
1	0	120	88	158
2	-	0	48	104
3	-	-	0	84
4	-	-	-	0

in m[1,1] i.e. A1 , nothing is multiplied, hence it can be taken as zero

m[1,2] = A1. A2

    (5X4)   (4X6)

Total cost of multiplication = 5 *4* 6 = 120

m[1,3] = A1.A2.A3

s

	1	2	3	4
1	-	1	1	3
2	-	-	2	3
3	-	-	-	3
4	-	-	-	-

Two possibilities: A1.(A2.A3) or (A1.A2).A3

    (5X4)   (4X6) (6X2)

for A1.(A2.A3) --> m[1,1] + m[2,3] + (5*4*2)

for (A1.A2).A3 --> m[1,2] + m[3,3] + (5*6*2)

0 + 48 + 40

120 + 0 + 60

    88

    180

Similarly, m[2,4]

formula:

A2.(A3.A4)   (A2.A3).A4

m[i,j] = m[i,k] + m[k+1, j] + di-1 * dk * dj

(4X6) (6X2)(2X7)   (4X6) (6X2)(2X7)

for A2.(A3.A4)   --> m[2,2] + m[3,4] + (4*6*7)

for (A2.A3).A4 --> m[2,3] + m[4,4] + (4*2*7)

we are generating n(n -1)/2 elements

0 + 84 + 168

48 + 0 + 56

time complexity = O(n^3)

    252

    104

m[1,4]

		min{m[1,1] + m[2,4] + (5*4*7), m[1,2] + m [3,4] + (5*6*7), m[1,3] + m[4,4] + (5*2*7)}	
		min{0+104+140, 120 + 84+210, 88+70}	
		min{244, 414, 158}	
60	**Matrix chain multiplication - A few pointers**		
	Condition of the multiplication: The number of columns in the first matrix involved in the multiplication must be equal to the number of rows in the second matrix		
A=	a11 a12 a13	2X3 dimension	
	a21 a22 a23		
B=	b11 b12	3X2 dimension	
	b21 b22		
	b31 b32		
A*B =	a11*b11 + a12*b21 + a13*b31 a11*b12 + a12*b22 + a13*b32	12 multiplications (2*3*2)	
	a21*b11 + a22*b21 + a23*b31 a21*b12 + a22*b22 + a31*b32	2X2 dimensions of the resultant matrix	
	A1 X A2 X A3 {Multiplication of more than two matrices}		
	2X3 3X4 4X2		
	d0 d1. d1 d2 d2 d3		
	Same answer by the two following methods (Associative property)		
	Method 1: (A1 X A2) X A3	**Method 2:** A1 X (A2 X A3)	
	2X3 3X4 i.e (2*3*4) = 24 multiplications for A1 X A2	2X3 3X4 4X2	
	Now, (A1 X A2) X A3 would require (2*4*2) = 16 multiplications	A2 X A3 requires (3*4*2) = 24 multiplications	
	Thus, altogether 40 multiplications are required	A1 X (A2 X A3) requires (2*3*2) = 12 multiplications	
		Altogether, 36 multiplications are needed here.	
	Now, dynamic programming asks us to find all the possible methods for matrix multiplication and check which one costs the minimum --> thsi implies that for 10 matrices, there would be numerous methods and we would have to check for all before proceeding with any one of them. Thus, we need a formula to check all that		
	We need to find C[1,3]		
	Method 1: (A1 X A2) X A3	**Method 2:** A1 X (A2 X A3)	
	C[1,2] = 24; C[3,3] = 0	C[1,1] = 0; C[2,3] = 24	

	C[1,2] + C[3,3] + d0*d2*d3 = 40	C[1,1] + C[2,3] + d0*d1*d3 = 36						
	C[i,j] = C[i, k] + C[k+1, j] + di-1 * dk * dj							
	After generalization,							
	C[i,j] = min { C[i,k] + C[k+1,j] + di-1 * dk * dj}							
	where i<=k<j							
	A1 X A2 X A3 X A4							
	d0 d1 d1 d2 d2 d3 d3 d4							
	Check which method works the best for the above matrix chain multiplication	2n C n / n + 1 multiplications are possible where n = no. of matrices - 1						
	1. A1 (A2 (A3A4))	Modified formula: 2(n-1) C (n-1) / n						
	2. A1 ((A2A3)A4)	Now, for n = 4, 2*3C3 / 4 = 6*5*4/3*2*1 / 4 = 5						
	3. (A1A2)(A3A4)	n = 5, 14 multiplications						
	4. (A1(A2A3))A4							
	5. ((A1A2)A3)A4							
	Applying the formula:							
4-1 = 3 values	C[1,4] = min { k = 1; C[1,1] + C[2,4] + d0*d1*d4,							
	k = 2; C[1,2] + C[3,4] + d0*d2*d4,							
	k = 3; C[1,3] + C[4,4] + d0*d3*d4}							
	1<= k < 4							
	1. A1 (A2A3A4)							
	2. (A1 A2) (A3 A4)							
	3. (A1A2A3) A4							
	here, C[1,1] = 0; C[4,4] = 0							
4-2 = 2 values	C[2,4] = min{k = 2; C[2,2] + C[3,4] + d1*d2*d4							
	k = 3; C[2,3] + C[4,4] + d1*d3*d4}							
	2<=k<4							

4-3 = 1 value	C[3,4] = C[3,3] + C[4,4] + d2*d3*d4			
	A1 X A2 X A3 X A4			
	3X2 2X4 4X2 2X5			
	d0 d1 d1 d2 d2 d3 d3 d4			
	As we notice that there is a repetition of the values needed , such as C[3,4] or C[4,4], there is unneccessary calculation, we are repeating, thus we should use a table (4X4)			

C table

	1	2	3	4	
					C[1,2] = min{k=1; C[1,1] + C[2,2] + d0*d1*d2
1	0	24	28	58	Thus, C[1,2] = 3*2*4 = 24
2	-	0	16	36	C[2,3] = min{k = 2; C[2,2] + C[3,3] + d1*d2*d3
3	-	-	0	40	Thus, C[2,3] = 2*4*2 = 16
4	-	-	-	0	C[3,4] = d2*d3*d4 = 4*2*5 = 40
					C[1,3] = min{k=1; C[1,1] + C[2,3] + d0*d1*d3

k table

	1	2	3	4	
					k = 2; C[1,2] + C[3,3] + d0*d2*d3
1	-	1	1	3	C[1,3] = min{16 + 3*2*2, 24 + 3*4*2}
2	-	-	2	3	C[1,3] = min{28, 48} = 28
3	-	-	-	3	
4	-	-	-	-	C[2,4] = min{C[2,2] + C[3,4] + d1*d2*d4,
					C[2,3] + C[4,4] + d1*d3*d4}
	The result shows that we need to do minimum of 58 multiplications to get the result of A1 X A2 X A3 X A4				C[2,4] = min{40 + 2*4*5 , 16 + 2*2*5}
	The k table will give the paranthesization				C[2,4] = min{80, 36} = 36
	((A1) (A2 A3))(A4)				
	How much time it has taken ? 1+2+3+4 = 4(5) /2 i.e. n(n+1)/2 ~ n^2				C[1,4] = min{k = 1; C[1,1] + C[2, 4] + d0*d1*d4,
	we also tried n posisble values of k to compute this value, thus time taken is n^2 * n i.e. O(n^3)				k = 2; C[1,2] + C[3,4] + d0*d2*d4,
					k=3; C[1,3] + C[4,4] + d0*d3*d4}
					C[1,4] = min{36 + 3*2*5, 24 + 40 + 3*4*5, 28 + 3*2*5}
					C[1,4] = min{66, 124, 58} = 58
61	**Matrix chain multiplication Program**				
	A1 X A2 X A3 XA4				main{
	5X4 4X6 6X2 2X7				int n = 5;

		int P[] = {5, 4, 6, 2, 7};					
	P = { 5,4,6,2,7}	int m[5][5] = {0};					
		int s[5][5] = {0};					
		int j, min, q;					
		for(int d = 1; d < n -1; d++)

		if(q < min)					
		{					
		min = q;					
		s[i][j] = k;					
		}					
		}					
		m[i][j] = min;					
		}					
		}					
		cout << m[1][n -1];					
		}					
62	**Single source shortest path (Bellman Ford Algorithm)**	Example of Bellman Ford algorithm:					
	For doing this, we already have Dijkstra algorithm but it may not eork correctly if we have negative weights, thus we need some other method that works with negative weights	edges --> (3,2)(4,3)(1,4)(1,2)					
	Bellman Ford algorithm says that we should relax the edges N-1 times where the number of vertices is equal to N	mark source vertex 1 as 0 and rest all as infinity					
	|V| = N = 7	there are 4 vertices, so we should relax allt the edges for 3 times					
	So, we should relax them for |V| - 1 times	First iteration:					
	so, we would cover all possible paths even the longest path	for (3,2) --> infinity - 10 is infinity only, so no change					

Relaxation means between a pair of vertices u and v if there is an edge, then check if:	for (4,3) --> infinity + 3 s infinity only, so no change					
if(d[u] + C(u,v) < d[v]){	for (1,4), 0 +5 < infinity , thus vertex 4 is updated to 5					
d[v] = d[u] + C(u,v)}	for (1,2) 0 + 4 < infinity, thus vertex 2 is updated to 4					
edgeList --> (1,2)(1,3)(1,4)(2,5)(3,2)(3,5)(4,3)(4,6)(5,7)(6,7)	Second iteration:					
Now, I have to relax these edges for |V| - 1 i.e. 6 times	for (3,2), vertex 2 is already 4, which is less than d[u] + C(u,v) in this case					
Initially, mark the distance for source vertex as 0 and for the rest of the vertices as infinity	for (4,3) vertex 3 is updated to 5+3 = 8					
Now, let's relax edge (1,2)	for (1,4)--> no change					
here, d[u] = 0; d[v] = infinity; C(u,v) = 6	for(1,2) --> no change					
0 + 6 < infinity ; thus d[v] = 6	Third iteration					
for vertex 2, distance is 6;	for(3,2), 8 - 10 = -2 < d[v] which is 4 right now; thus updated for vertex 2 as -2					
similarly, relaxing (1,3); thus its distance is updated to 5 from infinity	for the rest of the edges there won't be any change					
in similar way, (1,4) is relaxed, following that the distance of vertex 4 is updated to 5 from infinity	results obtained :					
Now, relaxing (2,5); d[u] = 6 ; C(u,v) = -1; d[v] = infinity	vertex 1 --> 0					
the distance (2,5) is updated to 6 - 1 = 5	vertex 2 --> -2					
similarly, relaxing (3,2) ; d[u] = 5, C(u,v) = -2, d[v] = 6	vertex 3 --> 8					
5 - 2 = 3 < 6 thus, d[v] is updated here to 3 i.e. at vertex 2 , distance is updated to 3	vertex 4 --> 5					
Now, relaxing (3,5), d[u] = 5 , C(u,v) = 1, d[v] = 5 here d[u] + C(u,v) is not smaller than d[v] hence the distance of vertex 5 is not modified	Now, if I relax one more time extra, there's no change					
Moving to (4,3), relaxing it --> d[u] = 5, C(u,v) = -2; d[v] = 5, d[u] + C(u,v) = 3 < d[v] hence distance of vertex 3 is updated to 3	**Drawback of Bellman Ford algorithm:**					
following this (4,6) is relaxed again and checked, d[u] = 5, C(u,v) = -1; thus distance of vertex 6 is updated to 5-1 = 4	let us an edge(2,4) in the above example					
Now, relaxing (5,7), d[u] = 5; C(u,v) = 3; d[v] = infinity	we see even after N-1 iterations, there is one vertex changing, we note that there's a problem					
thus, d[v] is updated to 8 for edge (5,7)	the reason is that there is a cycle of edges where total weight of edges is negative i.e. 5 + 3+ (-10) = -2 , thus graph cannot be solved					
moving to (6,7), d[u] = 4, C(u,v) = 3; d[v] = 8	hence, for a negative weighted cycle , the bellman ford algorithm fails					

d[v] is updated to 7 here for edge (6,7)

let us continue second time;

there won't be any change in (1,2), (1,3), (1,4)

when we check for (2,5); d[u] = 3 C(u,v) = -1 d[v] = 5; d[v] for edge (2,5) is updated to 2

similarly, for edge (3,2), the value is change to 3 - 2 = 1; earlier it was 3

(4,3) and (4,6), there's no change

for (5,7) d[u] has changed from 5 to 2; thus d[v] changes to 2 + 3 = 5

for (6,7) there won't be any change

let us continue third time;

there won't be any change in (1,2), (1,3), (1,4),

when we check for (2,5); d[u] = 1 C(u,v) = -1 d[v] = 2; d[v] for edge (2,5) is updated to 0

for (3,2) there own't be any change

for (3,5) again thee won't be any change

for (4,3), (4,6) --> no change

for (5,7) d[v] gets updated to 0 + 3 = 3

for (6,7) --> no change

let us check for fourth time,

we notice for all edges --> no change

results obtained:

vertex 1 --> 0

vertex 2 --> 1

vertex 3 --> 3

vertex 4 --> 5

vertex 5 --> 0

vertex 6 --> 4

vertex 7 --> 3

so, finally these are the shortest paths

time complexity: O(|E|(|V| - 1)) ~ O(|V||E|) ~ O(N^2)

If it is a complete graph, that is between every two vertex there is an edge, then number of edges is N(N - 1) / 2

i.e. |E| = N(N - 1) /2

then time complexity = O(|E||V|) O(N((N -1)/2)(N - 1)) ~ O (N^3)

63 0/1 Knapsack Problem

m = 8; n = 4 where m is the capacity of the bag

P = {1, 2, 5, 6}

w = (2, 3, 4, 5}

Have to give a solution of what all should be included to maximize profit

x can be either 0 or 1; we cannot take fraction of an object

x would be like {1, 0,1....}

sum of profits is maximized i.e. max{sum(P_ix_i)}

sum(w_ix_i) <= m

2^4 solutions possible i.e. n^4 solutions

let us use tabulation method

as the capacity is 8 so we would take 0-8 columns and 0-5 rows

V			0	1	2	3	4	5	6	7	8
P	W	0	0	0	0	0	0	0	0	0
1	2	1	0	0	1	1	1	1	1	1	1
2	3	2	0	0	1	2	2	3	3	3	3
5	4	3	0	0	1	2	5	5	6	7	7
6	5	4	0	0	1	2	5	6	6	7	8

V[i,w] = max{V[i-1, w], V[i -1, w-w[i]]+ P[i]}

V[4,1] = max{V[3,1] , V[3, 1 - 5] + 6} = max{V[3,1], V[3,-4] + 6}

V[3,-4] is an undefined location; thus, V[4,1] is equal to V[3,1]

FROM THE ABOVE FORMULA WE DEDUCE THAT UPTO 5TH WEIGHT, WE WOULD BE GETTING A NEGATIVE NUMBER

so, we fill these values as it is from previous row until column 4

for 5th column, V[4,5] = max{V[3,5], V[3,0] + 6} = max{5, 0 + 6} = 6

V[4,6] = max{V[3,6] , V[3, 1] + 6} = max{6, 6} --> so take 6 only

V[4,7] = max{V[3,7], V[3,2] + 6} = max{7,7} = 7

V[4,8] = max{V[3,8], V[3,3] +6} = max{7, 2 + 6} = max{7,8} = 8

	Now, we need to write down x1, x2, x3 and x4 values						
	let us come with maximum profit i.e. 8 which we got only by including 4th object						
	thus x4 = 1; remaining profit = 8 - 6 = 2						
	now, check for object 3, if there is a value 2; check if the value 2 is there in for object 2 as well at the same place, if yes, then object 3 was not taken i.e. x3 = 0; if the same 2 is there for object 1 then x2 = 0 else x2 = 1						
	here, x3 = 0						
	x2 = 1						
	x1 = 0 as the remainng profit is 0						
	x = {0 1 0 1} for maximizing the profit						
	let us use sets method						
	we will prepare sets of P and w						
	s0 = {(0,0)}						
	s0(1) = {(1,2)} here, we added first object to elements of set s0						
	s1 = {(0,0),(1,2)} merged the above two sets to get s1						
	s1(1) = {(2,3), (3,5)} , added second object to elements of s1						
	s2 = {(0,0),(1,2)(2,3),(3,5)} merged the above two sets to get s2						
	s2(1) = {(5,4),(6,6),(7,7),(8,9)}						
	s3 = {(0,0),(1,2),(2,3),(3,5),(5,4),(6,6),(7,7)} removed (8,9) as it exceeded the permitted limit						
	in the above set, we notice that as profit increases , weight increases, but at (5,4) profit has increased from (3,5) whereas weight has decreased						
	thus, we discard (3,5) with lesser profit {dominance rule}						
	so, s3 = {(0,0),(1,2),(2,3),(5,4),(6,6),(7,7)}						
	now, considering the fourth object,						
	s3(1) = {(6,5),(7,7),(8,8)(11,9),(12,11)(13,12)}						
	s4 = {(0,0),(1,2),(2,3),(5,4),(6,6), (7,7), (8,8)} merged above two sets and removed elements using dominance rule and those exceeding the weight limits						
	time taken is almost (2^n)						
	maximum order is (8,8)						
	(8,8) belongs to s4						

	check whether it belongs to s3 ---> it does not, hence object 4 is included							
	now (8,8) - (6,5) = (2,3)							
	(2,3) --> check if it belongs to s3 --> yes, check whether it belongs to s2 -> yes, thus object 3 is not included --> now, check if it belongs to s1 --> no, that means object 2 is included and object 1 is not							
	2-2, 3-3 = (0,0)							
	(0,0) belongs to set 1 and set 0 as well therefore object 1 is not included							
	x = {0 1 0 1}							
64	**0/1 Knapsack Dynamic Programming**							
		main()						
	P = {0, 1, 2, 5, 6}	{						
	wt = {0, 2, 3, 4, 5}	int P[5] = {0, 1, 2, 5, 6}						
		int wt[5] = {0, 2, 3, 4, 5}						
	n = 4, m = 8	int m = 8, n = 4;						
		int k[5][9];						
	i = n ; j = m;							
	while(i > 0 && j > 0) {	for(int i = 0; i <= n; i++)						
	if(k[i][j] == k[i-1][j])	{						
	{	for(int w = 0; w <= m; w++)						
	cout << i << "=0" << endl; i--;	{						
	}	if(i==0 || w == 0)						
	else {	{						
	cout << i << "=1" << endl; i--; j = j - wt[i];	k[i][w] = 0;						
	}	} else if (wt[i] <= w)						
	}	{						
		k[i][w] = max{P[i] + k[i-1][w - wt[i]], k[i-1]w};						
		}						
		else						
		{						
		k[i][w] = k[i-1][w];						
		}						
		}						
		cout<<k[n][w];						

						}

65 Optimal Binary Search Tree

keys --> 10, 20, 30, 40, 50, 60, 70

time taken for searching a particular key in a BST is logn where n is the number of nodes and logn is the minimum height of the tree

if the target key is not in the tree, the search would be unsuccessful

2n C n / n + 1 binary searches are possible for n keys

cost is dependent upon number of comparisons needed

A balanced binary search tree would require the minimum number of comparisons

In an optimal binary search tree problem, in addition to the number of comparisons we also consider the frequency of search of those keys

	1	2	3	4		C[0,2]
keys	10	20	30	40		10 20
frequency	4	2	6	3		4 2

j

		0	1	2	3	4	
i	0	0	4	8_1	20_3	26_3	l = j - i = 0
	1	0	0	2	10_3	16_3	0 - 0 = 0
	2	0	0	0	6	12_3	1 - 1 = 0
	3	0	0	0	0	3	2 - 2 = 0
	4	0	0	0	0	0	3 - 3 = 0
							4 - 4 = 0

w(0,4) = sum(f(i)) where 0<=i <= 4	set up cost for all diagonala values as 0;
calculating For first case, C[0,2] = C[0,0] + C[1,2] + w[0,2]	l = j - i = 1
C[0,2] = 0 + 2 + 6	C[0,1] i.e. considering only key 1
C[0,2] = 8	cost is 4
Similarly, calculating cost C[0,2] in the second case = C[0,1] + C[2,2] + w[0,2]	similarly, C[1,2] i.e. considering only second key
here, C[0,2] = 4 + 0 + 6 = 10	cost is 2
	Similarly, C[2,3] = 6 and C[3,4] = 3

	C[1,3] (CASE 1 when 20 is the root and 30 is it's right node) = 2*1 + 6* 2 = 14	Now, l = j - i = 2 i.e. we would consider 2 keys at a time					
	C[1,3] (CASE 2 when 30 is the root and 20 is its left node) = 6*1 + 2*2 = 10	i.e C[0,2] , C[1,3] and C[2,4]					
		C[0,2]: key 10 and 20 with frequency 4 and 2 respectively					
	C[2,4] (CASE 1 when 30 is the root and 40 is its right node) = 6*1 + 3*2 = 12	Two possibilities: 10 in the root and 20 it's right node OR 20 in the root and 10 it's left node					
	C[2,4] (CASE 2 when 40 is the root and 30 is on the left) = 3*1 + 6*2 = 15	for first case: Cost = 4*1 + 2*2 = 8					
		for second case: Cost = 2*1 + 4*2 = 10					
	l = j - i = 3	minimum cost is 8 and the root is 1					
	C[0,3] , C[1,4] for C[0,3], w[0,3] = 12						
	For C[0,3] , (CASE 1 : 10 as a root and 20 it's right node, 30 is the right node of 20) = C[0,0] + C[1,3] + w[0,3] = 0 + 10 + 12 = 22						
	(CASE 2, 10 as a root and 30 it's right node, 20 is the left node of 30)						
	(CASE 3 when 20 is the root, 10 it's left child and 30 it's right child) = C[0,1] + C[2,3] + 12 = 4 + 6 + 12 = 22						
	(CASE 4 when 30 is the root, 20 is the left child and 10 is its left child) = C[0,2] + C[3,3] + 12 = 8 + 0 + 12 = 20						
	(CASE 5 when 30 is the root, 10 is its left child and 20 is the right child of 10)						
	C[1,4] ; w[1,4] = 11						
	C[1,4] = min{C[1,1] + C[2,4] + 11; C[1,2] + C[3,4] + 11; C[1,3] + C[4,4] + 11}						
	C[1,4] = min{0 + 12 + 11; 2 + 3 + 11; 10 + 0 + 11} = min{23, 16, 21} = 16						
	l = j - i = 4 = 4 - 0 ; w[0,4] = 15						
	C[0,4] = min{ C[0,0] + C[1,4] + 15; C[0,1] + C[2,4] + 15; C[0,2] + C[3,4] + 15; C[0,3] + C[4,4] + 15} = min { 0 + 16 + 15; 4 + 12 + 15; 8 + 3 + 15; 20 + 0 + 15} = min{31, 31, 26, 35} = 26						

	root[0,4] = 3	
	then left child is root[0,2] and right child is root[3,4]	
	root[0,2] is 1 and root[3,4] is 4; root[3,4] is further subdivided into root[3,3] and root[4,4]	
	root[0,2] is further divided into root[0,0] and root[1,2]	
	root[1,2] is the second key and its further divided into root[1,1] and root[2,2]	
	C[i,j] = min{ C[i,k-1] + C[k,j]} + w(i,j) where i<k<= j	
66	**Optimal Binary Search Tree Successful And Unsuccessful Probability**	
	Unsuccessful nodes can be represented by dummy nodes	
	If there are n keys, there ould be n+1 square dummy nodes	
	Successful search probability represents probability of getting a given key in the lot whereas unsuccessul search probability represents a range of values of the key	
	cost [0,n] = P_i * level(a_i) + Q_i * (level(e_i) - 1)	
	this cost value is calculated over $1 <= i <= n$ for successful searches (P_i) and $0 <= i <= n$ for unsuccesful searches (Q_i)	
	the above cost is minimized for optimal binary search tree	
	Is it possible that we find out the best tree without calculating the cost of all the trees	
	Let's use dynamic programming to find out the minimum cost arrangement without actually computing cost for each binary search tree possible	
	C[i,j] = min{ C[i,k-1] + C[k,j]} + w(i,j) where i<k<= j	
	Let us consider it for just three nodes	
	i.e. C[0,3] = min{C[0,0] + C[1,3] + w[0,3], C[0,1] + C[2,3] + w[0,3], C[0,2] + C[3,3] + w[0,3] } where 0<k<=3	
	C[0,0] = C[3,3] = 0	
	C[1,3] = min{C[1,1] + C[2,3] , C[1,2] + C[3,3]} + w[1,3] where 1 < k <= 3	

	Here, C[1,1] = C[3,3] = 0										
	Values we need, C[0,0], C[1,1], C[2,2], C[3,3], C[0,1], C[1,2], C[2,3], C[0,2], C[1,3], C[0,3]										
	i,j										
j - i = 0	C[0,0] C[1,1] C[2,2] C[3,3]				$w[0,2] = q0 + p1 + q1 + p2 + q2$						
j - i = 1	C[0,1] C[1,2] C[2,3]				$w[0,3] = q0 + p1 + q1 + p2 + q2 + p3 + q3$						
j - i = 2	C[0,2] C[1,3]				thus, $w[0,3] = w[0,2] + p3 + q3$						
j - i = 3	C[0,3]				$w[i, j] = w[i, j-1] + p_j + q_j$						
	we basically need to find the cost, weight and the root at each stage										

	0	1	2	3	4	j -->	0	1	2	3	4
keys		10	20	30	40	j - i = 0	$w_{00} = q0 = 2$ $C_{00} = 0$ $r_{00} = 0$	$w_{11} = q1 = 3$ $C_{11} = 0$ $r_{11} = 0$	$w_{22} = q2 = 1$ $C_{22} = 0$ $r_{22} = 0$	$w_{33} = q3 = 1$ $C_{33} = 0$ $= 0$ r_{33}	$w_{44} = q4 = 1$ $C_{44} = 0$ $r_{44} = 0$
p_i		3	3	1	1	j - i = 1	$w_{01} = w[0,0] + p1 + q1 = 8$ $C_{01} = 8$ $r_{01} = 1$	$w_{12} = 7$ $= 7$ C_{12} $r_{12} = 2$	$w_{23} = 3$ $C_{23} = 3$ $r_{23} = 3$	$w_{34} = 3$ $C_{34} = 3$ $= 4$ r_{34}	
q_i	2	3	1	1	1	j - i = 2	$w_{02} = 12$ $C_{02} = 19$ $r_{02} = 1$	$w_{12} = 9$ C_{12} $= 12$ $r_{12} = 2$	$w_{24} = 5$ C_{24} $= 8$ $r_{24} = 3$		
						j - i = 3	$w_{03} = 14$ $C_{03} = 25$ $r_{03} = 2$	$w_{14} = 11$ $C_{14} = 19$ $r_{14} = 2$			
						j - i = 4	$w_{04} = 16$ $C_{04} = 32$ $r_{04} = 2$				

	Finally , the tree looks like the below tree:										
	r[0,4] = 20										
r[0,1] = 10						r[2,4] = 30					
						r[3,4] = 40					
67	**Travelling Salesman Problem Using Dynamic Programming**										
	A directed weighted graph is given and every edge is having weight										
	we have to start from some vertex and travel all the vertices and return back to the starting vertex and the cost of travelling should be minimum										

	1	2	3	4							
1	0	10	15	20							
2	5	0	9	10							
3	6	13	0	12							
4	8	8	9	0							
	$g(i,s) = \min \{ C_{ik} + g(k, s - \{k\})\}$ where k belongs to s										
	$g(1, \{2,3,4\}) = \min\{ C_{1k} + g(k, \{2,3,4\} - \{k\})\}$ where k belongs to {2,3,4}				Now, this is a recursive formula for which result can be obtained by generating recursive tree						
	vertex 1										
here, costs can be taken from given table	vertex 2 $g(1,2) = \min\{ C_{12} + g(2, \{3,4\})\}$; C12 = 10				vertex 3 $g(1,3) = \min\{C_{13} + g(3, \{2,4\})\}$; C13 = 15		vertex 4 g (1,4) = C14 + g(4, {2,3})}; C14 = 20				
	vertex 3 C23 + g(3, {4}) || vertex 4 C24 + g(4, {3}); C23 = 9, C24 = 10				vertex 2 C32 + g(2, {4}) || vertex 4 C34 + g(4, {2}); C32 = 13 , C34 = 12		vertex 2 C42 + g(2, {3}) || vertex 3 C43 + g(3, {2}); C42 = 8, C43 = 9				
	g(3,{4}) = C34 + g(4, phi i.e. nothing) ; g(4, {3}) = C43 + g(3, phi); C34 = 12, C43 = 9; g(4, phi) ~ g(4,1) = 8; similarly, g(3, phi) = 6				g(2, {4}) = C24 + g(4, phi) ; g(4,{2}) = C42 + g(2, phi); C24 = 10, C42 = 8, g(4, phi) = 8, g(2, phi) = 5		g(2,{3}) = C23 + g(3, phi) ; g(3, {2}) = C32 + g(2, phi); C23 = 9, C32 = 13; g(3, phi) = 6, g(2, phi) = 5				
	we use tabular method to solve these from bottom to top actually,										
	g(2,phi) = 5										
	g(3, phi) = 6										
	g(4, phi) = 8										
	g(2,{3}) = 15										
	g(2,{4}) = 18										
	g(3,{2}) = 18										
	g(3,{4}) = 20										
	g(4,{2}) = 13										

	g(4,{3}) = 15											
	g(2, {3,4}) = minimum of the options = 25											
	g(3, {2,4}) = 25											
	g(4, {2,3}) = 23											
	g(1, {2,3,4}) = 35											
68	**Reliability Design Problem**											
	we have to set up a system											
	system consists of certain devices											
	Reliability here means what is the probability of a device working perfectly / good				Example:							
DEVICES	D1	D2	D3	D4	Di	Ci	ri	ui				
COST	C1	C2	C3	C4	D1	30	0.9	2				
RELIABILITY	r1	r2	r3	r4	D2	15	0.8	3				
	0.9	0.9	0.9	0.9	D3	20	0.5	3				
					C = 105							
	Reliability of the entire system = product of individual reliability of the devices = 0.9^4 = 0.6561 i.e. 35% chance that the system might experience a failure				At least one copy of each device must be taken, so C1 + C2 + C3 = 30 + 15 + 20 = 65							
	In case of failure, system is designed to have parallel copies of devices as a back up				Remaining amount = C - sum(Ci) = 105 - 65 = 40							
	here, r1 = 0.9				if I spend the entire remaining amount on D1, I would be able to purchase 1 D1 device							
	1 - r1 = 1 - 0.9 = 0.1				**ui = [C - sum(Ci) / Ci] + 1 copies of any device Di**							
	$(1 - r1)^3 = 0.1^3 = 0.001$				for D2, 40/15 = 2 + 1 = 3 copies							
	probability that three copies are working perfectly = $1 - (1 - r1)^3$ = 0.999				for D3, 40/20 = 2 + 1 = 3 copies							
	Reliability has improved by using a parallel system				Solving this is similar to the set method of 0/1 knapsack problem, let's delve deeper							
	How many devices should I buy within the given cost such that the system's reliability is maximized				(R,C)							
					s0 = {(1,0)}							
					consider D1, s1₁ = {(0.9, 30)}							
					if we take 2 copies of the firstd evice D1 , s1₂ = {(1(1-0.9)^2)} = 1 - 0.1^2 = 0.99							
					thus, s1₂ = {(0.99, 60)}							

		$s1 = \{(0.9, 30), (0.99, 60)\}$					
		consider D2 one copy, $s2_1 = \{(0.72,45), (0.792, 75)\}$					
		Taking 2 copies of D2, $s2_2 = 1 - (1 - r2)^2 = 1 - (1 - 0.8)^2 = 1 - 0.04 = 0.96$					
		$\{(0.864, 60), (0.9504, 90)\}$					
		in the last case, remaining cost = 105 - 90 = 15 ; we cannot purchase D3 as its cost is 20 which is more than our remaining amount; so we would discard that set option as. it is unfeasible					
		consider 3 copies of D2, reliability = $1 - (1 - r2)^3 = 1 - (1 - 0.8)^3 = 1 - 0.008 = 0.992$					
		$s2_3 = \{(0.8928, 75), (...., 105)\}$ --> second case is discarded as it is unfeasible					
		$s2 = \{(0.72,45), (0.792, 75), (0.864, 60), (0.8928, 75)\}$					
		in s2, the third case has cost decreased but reliability is increased, thus we would use domimance rule to remove / discard the third case					
		Now, consider one copy of D3, $s3_1 = \{(0.36,65), (0.432, 80), (0.4464, 95)\}$					
		$r3 = 0.5$; $1- (!-r3)^2 = 1- 0.25 = 0.75$					
		$s3_2 = \{(0.54, 85), (0.648, 100)\}$ the third case has cost exceeding 105 thus it has been discarded					
		Consider three copies; $1 - (1 - r3)^3 = 0.875$					
		$s3_3 = \{(0.63, 105)\}$					
		$s3 = \{(0.36,65), (0.432, 80), (0.4464, 95), (0.54, 85), (0.648, 100), (0.63, 105)\}$					
		Using dominance rule, $s3 = \{(0.36,65), (0.432, 80), (0.54, 85), (0.648, 100)\}$					
		Maximum reliability = 0.648 and the cost would be 100					
		for getting the number of copies of devices, go backward from 0.648, 100 ordered pair					
		which shows 1 copy of D1, 2 copies of D2, 2 copies of D3					
69	**Longest Common Subsequence (LCS)**						
	What is LCS?						

	LCS Using Recursion	
	LCS Using Memoization (to save time as recursion is time consuming)	
	LCS Using Dynamic Programming	
	String 1: a b c d e f g h i j	String1: a b d a c e
	String 2: e c d g i	String 2: b a b c e
	c d g i is the longest subsequence	b a c e and a b c e are the longest subsequences
	LCS Using recursion	
A	b d \0	int LCS(i,j)
		{
B	a b c d \0	if (A[i] == '\0' || B[j] == '\0')
		return 0;
		else if (A[i] == B[j])
		return 1 + LCS(i + 1, j + 1);
		else
		return max(LCS(i+1, j), LCS(i, j+1));
		}
	Recursion tree for the above example -	
	A[0] , B[0] : b, a : 2	
Call1	A[1], B[0] : d, a : 1	A[0], B[1]: b, b : 2
Call2	A[2], B[0] : \0 , a || A[1], B[1] : d, b : 1	1 + A[1], B[2] : 1 + d, c
Call3	0 || A[2], B[1] : \0, b || A[1], B[2] : d, c : 1	1 + A[2], B[2] || 1+ A[1], B[3]
Call 4	0 || 0 || A[2], B[2] : \0, c || A[1], B[3] : d, d : 1	1 + \0 || 1 + 1
	0 || 0 || 0 || 1 + A[2], B[4] : 1 + \0 : 1	
	The purpose of the above problem was to depict that there is an issue of overlapping. But, there is no reason for repeat recalls if we can store the answer of previous stage. Thus, we use memoization	
	LCS using memoization	
	a b c d \0	

		0	1	2	3	4
b	0	2	2	-	-	-
d	1	1	1	1	1	-
\0	2	0	0	0	-	0

Memoization can reduce the number of function calls : O(m X n) where m and n are the counts in String 1 and 2 respectively

LCS using dynamic programming

DP would follow bottom up approach and fill out the table top to bottom whereas in the previous approach we were following top down approach and filling the table in bottom up manner

if(A[i] == B[j])

A : b d

{

B : a b c d

LCS[i,j] = 1 + LCS[i - 1, j - 1];

} else

		a	b	c	d
		0	1	2	3	4

{

LCS[i,j] = max(LCS(i - 1, j], LCS[i, j - 1])

		0	1	2	3	4
	0	0	0	0	0	0
b	1	0	0	1	1	1
d	2	0	0	1	1	2

}

if we trace our way back from 2 (d,d) above then we see that we go backwards diagonally to 1 (b,c) , then horizontally to 1 (b, b) and then diagonally back to 0 (0,a); thus there are two times we moved diagonally back i.e. b d is the LCS

str 1	s t o n e
str 2	l o n g e s t

		l	o	n	g	e	s	t
		0	1	2	3	4	5	6	7
0	0	0	0	0	0	0	0	0	0
s	1	0	0	0	0	0	0	1	1
t	2	0	0	0	0	0	0	1	2
o	3	0	0	1	1	1	1	1	2
n	4	0	0	1	2	2	2	2	2

e	5	0 0 1 2 2 3 3 3

LCS — Take the elements which came from a diagonal - o n e

70 Graph Traversals - BFS and DFS

Visiting a vertex

Exploration of a vertex - visiting all of the adjacent vertices

BFS: 1, 2, 4, 5, 3, 6, 7

DFS: 1, 2, 3, 6, 7, 4, 5

BFS: 1 4 2   3 5 8 7 10 9   6

Queue: Q 1 4 2 3 5 8 7 10 9   6

Breadth first search spanning tree -

```
                        1
                       4 2
              3   5   8   7
                      10 9
                       6
```

DFS: 1   4   3   10 9   2 8 7 5 6

Stack: *Depth first search spanning tree*

O(n) where n is the number of vertices	1

7	3
8	10 9 2
2	8
4	7
1	5
	6

71 Articulation point

Biconnected components

In a graph, if there is a vertex whose removal would segregate the graph into distinct components, then that vertex is called the articulation ppoint

To tackle articulation point, we need to extend an edge from vertex in one component to another

	How to find an articulation point in a graph?	Algorithm:					
	DFS: 1 2 3 4 5 6	Conduct depth first search and find depth first search spanning tree					
	d: 1 6 3 2 4 5	Mention the discovery times for each vertex					
	L: 1 1 1 1 3 3	We need to find the lowest discovery number to find any vertex by taking a back edge					
	u, v: parent, child then the lowest number of v i.e. L[v] >= d[u] then u is an articulaion point. This condition is true for all except the root.	Find out articulation point					
	The above algorithm is true for v = 5 and u = 3; hence 3 is the articulation point						
	If root has more than one child, then root is also an articulation point
